#### FOREWORD

The Forest Survey is a nation-wide activity of the Forest Service. The fivefold purpose of the Forest Survey is (1) to make a field inventory of the present supply of standing timber; (2) to find out how fast this supply is being increased through growth; (3) to find out how fast it is being diminished through industrial and domestic uses, windfall, fire, disease, and other causes; (4) to determine the present consumption and the probable future trend in requirements for forest products; and (5) to interpret and correlate these findings with existing and anticipated economic conditions, as an aid in formulating both private and public policies for use of land suitable for forest production.

The Forest Survey is conducted in the various regions by the forest experiment stations of the Forest Service. In Indiana the project is directed by the Central States Forest Experiment Station with headquarters in Columbus, Ohio.

This Survey Release presents the more significant preliminary statistics on the forest area and timber volume for each of the three regions of southern Indiana. A similar report will be published for the two northern Indiana regions. Later, an analytical report for the state will be published which will interpret statistics on forest area, timber-volume, growth, and drain in the light of existing and anticipated economic conditions.

LOCATION OF FOREST SURVEY REGIONS IN INDIANA

#### SIGNIFICANT FOREST AREA AND TIMBER VOLUME STATISTICS

#### FOR SOUTHERN INDIANA

In this report the forest statistics for Southern Indiana are shown separately for three principal subdivisions or regions. These have been established in such a way as to group counties that have similar forest, soil, and economic conditions. A brief description of the physiographic and economic characteristics of each region follows.

Lower Wabash.—The level or gently rolling lands bordering the lower reaches of the Wabash, White, and Patoka rivers are part of a large region extending into Illinois and Kentucky. The river valleys are wide and flat; elevation is almost wholly below 700 feet. Coal mining is an important activity, especially in the northern part. The southern three counties, called "The Pocket," produce fine timber and contain much of Indiana's original cypress swamp area. Corn and wheat are the principal agricultural crops.

Knobs.—This south-central region is a succession of lowlands and uplands running north and south in fairly narrow belts, and includes most of the state's unglaciated area. In the center, a belt of rugged upland extending into picturesque Brown County is famous for its wooded hills or "knobs." Much of the land is unsuited for agriculture; much of the farming is on a subsistence level. On the areas of rough topography where the top-soil has been largely washed away, cleared land is reverting to forest. Timber is an important product, but the stands have been seriously overcut.

Upland Flats.——In southeastern Indiana is an old glaciated upland area that extends into Ohio and also forms part of the outer Bluegrass region of Kentucky. Short, steep streams descending to the Ohio river have deeply trenched the southeastern border, but in the north and central part of the region fairly extensive poorly-drained flats occur. On the western edge a broad slope descends to a lowland area on the edge of the Knobs region. Typical forests of the poorly-drained uplands are composed chiefly of beech, sweetgum, and pin oak. A general farming system produces corn, wheat, and hay in the western section, while dairy products and tobacco are important in the east.

The total land area of Southern Indiana is 9.5 million acres, of which 2.9 million acres or 30 percent is forested. On the average, the counties in the Knobs region have the largest proportion of their land area in forest. Individually they range from 19 to 71 percent in forest and average 40 percent. In the Upland Flats region, forests occupy 28 percent of the land area and in the Lower Wabash region, 22 percent.

<sup>1/</sup> For a definition of forest land, see page 36.

Ninety-two percent of the forest land is privately owned. The Hoosier National Forest and several state forests and parks account for most of the remaining 8 percent. Practically all of the forest area can be classified as commercial; less than 50,000 acres are non-commercial in the sense that timber cutting is forbidden. This area is entirely in state parks, military reservations, and similar areas. Virtually no forest area is noncommercial because of poor timber-growing conditions.

The oak-hickory and mixed hardwood forest types occur on approximately four-fifths of the commercial forest area of the three regions. Hardwoods predominate, although pine, cypress, and redcedar are also found in the area.

Stands in which trees of saw-timber size predominate make up nearly half of the total commercial forest area. Pole-timber stands occupy about 35 percent of the commercial forest area, and seedling and sapling stands account for nearly all of the remaining 15 percent.

The total volume of saw timber in Southern Indiana is 6.4 billion board feet. Of this total, 1.8 billion board feet are in the Lower Wabash region, 3.4 billion in the Knobs region, and 1.2 in the Upland Flats region. The oaks make up about 42 percent of the total volume. Hickory with 10 percent and yellow-poplar and beech with about 8 percent each are also important from the standpoint of volume. Nearly 90 percent of the saw-timber volume occurs in stands classified as saw timber. Most of the remaining saw-timber volume occurs in scattered larger trees in pole-timber stands. Forty percent of the saw-timber volume is found in trees 12 to 14 inches d.b.h., and 30 percent is in trees 20 inches d.b.h. and larger.

This estimate of saw-timber volume is considerably higher than previous estimates. Some of this difference is due to the inclusion by the Forest Survey of the timber volume of heavily grazed woodlands lacre and larger in area where the tree crowns cover at least 10 percent of the ground space. This area, totaling 206 thousand acres and supporting 509 million board feet, is so heavily grazed that, unless livestock are kept out entirely it will eventually pass from the forest classification altogether. Presumably, a considerable part of this area was classified as pasture in the earlier estimates. In this report it is included in the commercial forest area.

The proportion of the saw-timber volume in high-quality logs is low. Only 11 percent of the hardwood volume is grade 1 and 2 logs, which provide the high-quality material required by the veneer, furniture, and cooperage industries. This condition is partly due to the large proportion of small saw-timber trees in the stand. On the average, no tree less than 14 inches d.b.h. can contain grade 1 or 2 volume. Forty percent of the board-foot volume occured in the 12- and

14-inch diameter classes, and therefore would be classified as grade 3. In time, however, much of this volume of small trees will grow into better-quality timber. The high proportion of the saw-timber volume in grade 3 logs is also partly due to the practice of cutting only the best trees in the stand and leaving the lower-quality trees.

The volume of the total forest growing stock (including the present and potentially merchantable portion of saw-timber trees and pole-timber trees) is 1.7 billion cubic feet. Of this, 1 billion cubic feet is in saw-timber trees and 0.7 billion in pole-timber trees. In addition to this growing stock, 0.9 billion cubic feet is in the limbs of saw-timber trees and in the sound portion of cull trees and trees of noncommercial species.

The average volume of saw timber per acre on all commercial forest land in Southern Indiana is 2,221 board feet. By regions these average board-foot volumes per acre vary as follows: Lower Wabash, 2,309; Knobs, 2,060; and Upland Flats, 2,671. Large saw-timber stands averaged 5,376 board feet per acre, and small saw-timber averaged 3,016 board feet per acre.

The average volume per acre of primary growing stock on commercial forest land was 582 cubic feet.

#### FOREST SURVEY PROCEDURE

The inventory of the forest resources of Southern Indiana was made during the period November 1949 to December 1950. The sampling procedure used involved an office study of aerial photographs and a field examination of randomly selected forest and nonforest plots.

The proportion of forest land in each county was obtained by placing a transparent template marked with uniformly spaced dots over aerial photographs and by counting the number of dots falling on forest and nonforest areas. The percentage of forest dots in a county, multiplied by the total area gave a preliminary estimate of the forest area. This was later adjusted after field examination indicated the number of plots that had changed from forest to nonforest since the date of aerial photography, and vice versa.

The location of a selected number of dots falling on forest land was marked on the photographs. The acre surrounding each marked dot was examined under stereoscope and was classified by stand-size class on the basis of the height, crown width, and number of trees on the plot. Plots to be examined in the field were randomly drawn from those classified under stereoscope. In making this selection the greatest weight was given to the stand-size classes containing the largest timber volume. In addition, several nonforest plots were selected for field examination to measure the movement of open land to forest since the date of photography.

The locations of the selected field plots were marked on the photographs, which were then sent to the field. Crews of two men each located these points on the ground. On forest land a 1/5 acre circular plot was established for which species, size, quality, and growth of trees were recorded.

The following tabulation gives the number of dots and plots examined for each of the three regions.

|  | Lower Wabash<br>Region | Knobs<br>Region | Upland<br>Flats<br>Region |
|--|------------------------|-----------------|---------------------------|
| Number of photo dots counted for forest-area determination | 24,134                 | 35,866          | 14,557                    |
| Number of plots stereoscopically examined on photos        | 1,943                  | 3,098           | 890                       |
| Number of forest plots field examined                      | 386                    | 675             | 170                       |
| Number of nonforest plots field examined                   | 65                     | 81              | 21                        |

#### ACCURACY OF DATA

Statistical analysis of forest-area and timber-volume data shows the following sampling errors for each of the three regions.

| Region       | Forest area |           | Saw-timber volume |           |  |
|--------------|-------------|-----------|-------------------|-----------|--|
|              | (M acres)   | (Percent) |                   | (Percent) |  |
|              |             |           | cu. ft.)          |           |  |
| Lower Wabash | 793         | 3.2       | 449.4             | 3.9       |  |
| Knobs        | 1,647       | 1.6       | 947.7             | 2.7       |  |
| Upland Flats | 434         | 4.0       | 275.9             | 5.6       |  |

These estimates of sampling error do not include errors resulting from the development and application of volume tables and cull factors, or from mistakes in measurement or judgment. All phases of field and office work were closely supervised to keep these errors to a minimum. Since the percentage error increases with each subdivision of the total, small acreages or volumes may have large errors and may therefore indicate only relative magnitudes.

<sup>1/</sup> At one standard deviation; i.e., the chances are two out of three that, if the survey were repeated, the total forest area or volume figures would not differ more than the errors shown in this table.

#### EXPLANATION OF TERMS USED

Forest land. — Includes (a) lands which are at least 10 percent stocked by trees of any size and capable of producing timber or other wood products, or of exerting an influence on the climate or on the water regime; (b) land from which the trees described in (a) have been removed to less than 10 percent stocking and which have not been developed for other use; (c) afforested areas; and (d) chaparral areas.

The minimum area that will qualify as forest land is 1 acre. Strips of timber must be at least 120 feet wide before the area will qualify as forest land. Conversely, clearings, streams, and unimproved treeless strips less than 1 acre in area or less than 120 feet in width within forest areas will be classified as forest land. Improved rights-of-way such as graded roads, railroads, or transmission lines will be classified as nonforest regardless of width.

Commercial forest land.—Forest land which is (a) producing, or physically capable of producing, usable crops of wood (usually saw timber), (b) economically available now or prospectively, and (c) not withdrawn from timber utilization.

Reserved forest land. -- Forest land that has been withdrawn from timber utilization through statute, ordinance, or administrative order.

Noncommercial forest land.—Forest land incapable of yielding usable wood products (usually saw timber) because of adverse site conditions, or so physically inaccessible as to be permanently unavailable economically, and not withdrawn for specified purposes.

#### Forest types

<u>Hardwood-pine</u>.—Forests of pines, oak, and other hardwoods in which pines comprise 25-50 percent of the dominant and codominant trees.

Oak-hickory.--Forests of hardwoods in which oaks and hickories comprise at least 50 percent of the dominant and codominant trees, except where pines comprise 25 percent or more, in which case the stand would be classified as hardwood-pine.

<u>Maple-beech.--Forests</u> in which at least 50 percent of the dominant and codominant trees are sugar maple or beech, singly or in combination.

<u>Mixed hardwoods.—Forests</u> in which 50 percent or more of the stand is upland ash, elm, basswood, walnut, soft maples, or associated species, singly or in combination, except where pines comprise 25 percent or more of the stand, in which case the stand would be classed as hardwood-pine.

<u>Pin oak flats.—Forests</u> on poorly drained flats in which 25 percent of the dominant and codominant trees are pin oaks.

<u>Lowland hardwoods.—Forests</u> on characteristically moist to wet sites where 50 percent or more of the stand is composed of sycamore, hackberry, honey locust, blackgum, sweetgum, southern cypress, ash, elm, willow, cottonwood, and red and silver maple, singly or in combination.

#### Tree classes

Saw-timber tree.--A live softwood (coniferous) tree at least 9.0 inches d.b.h. or live hardwood trees of commercial species at least 11.0 inches d.b.h., with a sound butt log at least 8 feet long, or with at least half of the gross volume of the tree in sound material.

<u>Pole-timber tree.--A</u> live, sound tree at least 5.0 inches d.b.h. but less than saw-timber size that gives promise of becoming a saw-timber tree.

<u>Cull tree.—A</u> live tree at least 5.0 inches d.b.h. that does not qualify as a saw-timber or pole-timber tree because of species, poor form, limbiness, rot, or other defect.

#### Volume estimates

Board-foot volume includes the volume of that portion of live saw-timber trees merchantable for sawlogs, but not less than 8 inches in diameter (see specification for grade 3 hardwood logs, page 38). Volume deductions have been made for rot, crook, and other defects. Board-foot volumes are shown in the International 1/4-inch log rule, which approximates green lumber tally.

#### Cubic-foot volume

Total volume includes the sound wood inside bark in both sound and cull living trees 5.0 inches d.b.h. and larger, from the stump to a minimum top diameter of 4.0 inches inside bark. It includes the upper stems of softwood trees and the upper stems and limbs of hardwoods.

Growing stock includes the volume of sound wood inside bark in (1) the sawlog portion of saw-timber trees, (2) the upper stem of softwood saw-timber trees to a minimum top diameter of 4.0 inches inside bark, (3) the upper stem of hardwood saw-timber trees to the limit of potential merchantability for saw timber, but never less than 4 inches inside bark, and (4) pole-timber trees to a minimum top diameter of 4.0 inches inside bark.

#### Stand-size class

Large saw timber.—Stands having a minimum net volume of 1500 board feet per acre in saw-timber trees, and having more than half of this volume in trees 15.0 inches d.b.h. and larger.

<u>Small saw timber.—Stands</u> having a net volume of 1500 board feet per acre in saw-timber trees, and having at least half of this volume in trees smaller than 15.0 inches d.b.h.

<u>Pole timber.—Stands</u> failing to meet the saw-timber stand specifications, but at least 10 percent stocked with pole-timber and larger trees and with at least half the minimum stocking in pole-timber trees.

<u>Seedlings and Saplings.—Stands</u> not qualifying as either sawtimber or pole-timber stands but having at least 150 seedlings and saplings of commercial species per acre.

Nonstocked .-- Commercial forest land not qualifying for any other class .

#### Hardwood log grades

Grade 1.—Butt logs at least 14.0 inches (uppers at least 16 inches) in diameter inside bark with five-sixths of the surface on the three best faces clear of defect in not more than two cuttings, (minimum length of cutting variable, 3-7 feet, depending upon log diameter and position in tree). Lumber from such logs will normally grade at least 60 percent No. 1 common and better.

Grade 2.-Logs at least 12 inches in diameter inside bark with two-thirds of the surface on the three best faces clear of defect in not more than three cuttings, (minimum length of cutting, 3 feet). Lumber from such logs will normally grade at least 35 percent No. 1 common and better.

Grade 3.—Merchantable logs at least 8.0 inches in diameter inside bark which do not meet the requirements of higher grades. Such logs will normally produce less than 35 percent No. 1 common and better lumber or will be suitable for ties or timbers.

#### Species listed

#### Softwoods

Virginia pine
Shortleaf pine
Pitch pine
White pine
Baldcypress
Redcedar
Hemlock

## Pinus virginianaPinus echinata

- Pinus echinata - Pinus rigida - Pinus strobus - Taxodium distichum

Taxodium distichum
Juniperus virginiana
Tsuga canadensis

#### Hardwoods

White oak Post oak group includes: Post oak Swamp white oak Swamp chestnut oak Overcup oak Bur oak Chinquapin oak Chestnut oak Black oak includes: Black oak Scarlet oak Northern red oak includes: Northern red oak Swamp red oak Cherrybark oak Other red oaks include: Southern red oak Pin oak Willow oak Water oak Shingle oak Hickory Soft maple includes: Red maple Silver maple Boxelder Sugar maple Sycamore (American) Ash Yellow-poplar

#### - Quercus alba

- Quercus stellata
- Quercus bicolor
- Quercus prinus
- Quercus lyrata
- Quercus macrocarpa
- Quercus muehlenbergii
- Quercus montana

- Quercus velutinaQuercus coccinea
- Quercus borealis
- Quercus falcata var. paqodaefolia - Quercus falcata var. leucophylla
- Quercus falcata
   Quercus palustris
   Quercus phellos
   Quercus nigra
   Quercus imbricaria
   Carya species
   Ulmus species
- Acer rubrum
   Acer saccharinum
   Acer negundo
   Acer saccharum
   Platanus occidentalis
   Fraxinus species
   Liriodendron tulipifera

Cottonwood (Eastern) Cottonwood (Swamp)

Sweetgum Blackgum

Blackgum (Swamp)

Black walnut

Populus deltoidesPopulus heteruphylla

- Liquidambar styraciflua

- Nyssa sylvatica

- Nyssa aquatica - Fagus grandifolia

- Juglans nigra

Other hardwoods - include all other commercial hardwood species.

Noncommercial species - include species that do not normally have commercial value such as hawthorn, redbud, hornbeam, hophornbeam, alder, and serviceberry.
